## ABSTRACT

TREC 61-106

Vertol Division, The Boeing Company, Morton, Pa., WIND TUNNEL TESTS AND FURTHER ANALYSIS OF THE FLOATING WING FUEL TANKS FOR HELICOPTER RANGE EXTENSION, VOL. 5 - Analysis of Stability, Control and Performance Characteristics by H. Neeb, D. Lawrence, and R. Johnstone, August 1961. 186 pp, incl. illus., tables. Contract (DA44-177-TC-550) USA TRECOM Proj. (9X38-09-006)

Unclassified Report

This report describes an analytical investigation of the stability and performance of a Boeing-Vertol H-21 tandem rotor helicopter equipped with floating wing fuel cells as a means of ferry range extension. The stability of the total system was studied with the wing located forward and directly under the helicopter center-of-gravity (cg). Two methods of stabilizing the wing oscillations about the hinge were studied: (a) A skewed hinge line, introducing a change in angle of attack as a function of the flapping disturbance, and (b) a geared trailing edge flap, mechanically linked to deflect when the wing flaps. Satisfactory stability was obtained with the wing positioned directly beneath the helicopter cg, using an un-skewed hinge line, and geared flaps. The forward wing location was found to be unsatisfactory from the standpoint of longitudinal stability for the light wing case. Flight simulator studies emphasize the need for additional lateral control to supplement that produced by the basic aircraft. It was found that full span, differential ailerons with deflections of  $2\frac{1}{2}$  degrees per inch of stick, provide satisfactory roll control and wing flapping angles. At a take-off weight of 25,900 lbs and with the wing in the aft position the ferry range is 1975 nautical miles.

FOREWORD

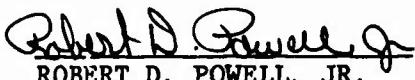

The U. S. Army, through the facilities of the U. S. Army Transportation Research Command, Fort Eustis, Virginia, has conducted a research program to determine a method for increasing the range of helicopters of the light-cargo type to 2,000 miles or more. The system that held the most promise was one wherein floating-wing fuel tanks were attached to the helicopter's fuselage.

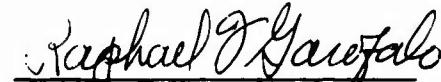

The report presented in the following pages is the fifth and last volume of the final report. This report contains the results of the analytical investigation of the stability, control, and performance characteristics of the floating wing fuel tank system. The conclusions presented in the report are concurred in by this Command.

A design and fabrication program is now under way as a follow-up to this research program.

$Z_{\dot{z}_H}$	Vertical Displacement Derivative with Respect to Vertical Velocity (Fuselage Rotor Contribution)

## SUMMARY

This report describes an analytical investigation of the stability and performance of a Boeing-Vertol H-21 tandem rotor helicopter equipped with floating wing fuel cells as a means of ferry range extension. The wings are hinged close to the root, and are in equilibrium under the steady-state aerodynamic and gravity forces, minimizing the root shear force and bending moments taken out at the attachment points.

The stability of the total system was studied with the wing located forward and directly under the helicopter center-of-gravity (cg). Two methods of stabilizing the wing oscillations about the hinge were studied: (a) a skewed hinge line, introducing a change in angle of attack as a function of the flapping disturbance, and (b) a geared trailing edge flap, mechanically linked to deflect when the wing flaps.

Satisfactory stability was obtained with the wing positioned directly beneath the helicopter cg, using an unskewed hinge line, and geared flaps. The forward wing location was found to be unsatisfactory from the standpoint of longitudinal stability for the light wing case.

Performance studies indicate that the aft wing position, as determined by stability criteria, is detrimental to the range. In order to insure a 2000 mile ferry range with the wing in a position to satisfy the stability requirements, the wing incidence relative to the helicopter was allowed to vary throughout the flight. Further studies will be conducted to determine the best compromise from both stability and overall performance considerations.

Flight simulator studies emphasize the need for additional lateral control to supplement that produced by the basic aircraft. It was found that full span, differential ailerons with deflections of 2-1/2 degrees per inch of stick provide satisfactory roll control and wing flapping angles.

The present floating wing has an aspect ratio of 8 and a span of 72 feet. The constant chord wing uses an NACA 4418 section. The maximum take-off weight of the system is 25,900 pounds, of which 14,800 pounds is fuel carried in the wings. At this weight and with the wing in the aft position the ferry range is 1975 nautical miles (n.mi.).

SUMMARY (Continued)

A forward wing position would increase the air miles per gallon and permit an increase in the take-off weight to 27,100 pounds, with a resulting range of 2400 n. mi.

## CONCLUSIONS AND RECOMMENDATIONS

The results of the present analysis indicate that the ferry range of a tandem rotor helicopter can be extended by the use of floating wing fuel cells. A configuration can be derived that has acceptable stability in cruising flight, at all weights.

Further work is necessary to refine the lateral-directional analysis to include the non-linear dihedral effect, and the work on both the lateral-directional and longitudinal stability should be extended to cover flight speeds below the cruise, down to minimum flying speed.

A conflict exists between wing position requirements for best stability on one hand, and optimum performance on the other. Longitudinal stability requires that the wing be situated near the cg and for maximum range it should be as far forward as possible to avoid rotor downwash. The existing analysis considers two wing positions - one in which the aerodynamic center is 14 feet ahead of the basic helicopter cg, the other in which the aerodynamic center is directly below the cg. It should be noted that the criterion of 2000 miles range was satisfied with the wing in the aft position only by allowing the wing incidence to vary throughout the flight. Further work will be done to optimize wing position, such that satisfactory longitudinal stability characteristics combined with minimum performance penalties may be achieved.

Flight simulator studies indicate that lateral control must be supplemented with full span differential ailerons having a gearing of 2-1/2 degrees per inch of lateral stick movement.

Performance calculations show that ferry range capabilities diminish as the wing is moved to the aft position. Maximum take-off weight, based on available take-off power, is decreased from 27,100 pounds to 25,900 pounds, and the range is reduced from 2400 n. mi. to 1975 n. mi.

## INTRODUCTION

The normal mission range of the modern helicopter is 400 n.mi., or less, while ideally, to achieve full global mobility, ferry ranges of 2000n. mi. or more are desired. In providing this range, the basic problem is to increase the lift-drag ratio and/or the fuel weight: empty weight ratio, without resorting to extensive structural modifications to the basic helicopter. While many research programs are today exploring high performance rotor systems, which show promise of yielding high lift-drag ratios, present-day helicopters exhibit values on the order of 4:1.

The Army's ferry range problem is concerned with present-day helicopters, in which no large improvements in lift drag ratio may be expected, so the alternative is to consider means of increasing the effective fuel-weight ratio. This must be achieved without drastic modification to the structure, or undue increase in the drag. Supplementary internal fuel tanks do not increase the range sufficiently; there is a prohibitive performance penalty resulting from the much increased rotor disc loading, and considerable internal modification is necessary to install them.

To be acceptable, any range extension system must meet the following basic criteria:

1. To be usable as a retro-fit item on existing helicopters, with a minimum increase in basic helicopter empty weight, it must entail the minimum of structural modification.
2. There must be no adverse effect on the stability of the aircraft at any weight.
3. Adequate control must be available at all flight speeds and weights.
4. To justify the development of the system, it must yield ultimate ferry ranges of 2000 n. mi. or better.

The floating wing fuel cell has been proposed as the most promising method of carrying the additional fuel without incurring severe drag and weight penalties. The supplementary tankage is fitted to the helicopter in the form of a pair of floating wings that are free to move vertically about hinges placed close inboard. The equilibrium

## INTRODUCTION (Continued)

condition for the wing in steady flight occurs when the static moments of lift and weight about the hinge are equal and opposite. In such a condition, the resultant vertical shear force at the hinge is very small, and the additional power required is a minimum, being just that necessary to overcome the wing drag and the wing-rotor interference drag. Thus the disc loading is not greatly increased, even though the weight of the system may be more than double that of a standard helicopter.

The problems to be dealt with in the design of the proposed range extension system can conveniently be discussed under the following four headings:

1. Overall system stability
2. Wing stability
3. Control
4. Performance

### OVERALL SYSTEM STABILITY:

The overall stability must be at least as good as that of the basic aircraft at all weights and speeds. There is a large separation between the maximum and minimum flying weights, and most of the fuel is to be carried in the wings, in the interests of achieving the best lift/drag ratio. Consequently, the moments of inertia, both of the systems as a whole and of the wing about its hinge, change markedly during the mission. Because of this wide variation in important system parameters it is difficult to achieve satisfactory stability in all flight regimes. The longitudinal stability is more sensitive to changes in weight, and to fore and aft location of the wing, and the final configuration will be a compromise between the requirements of range and longitudinal stability.

### WING STABILITY:

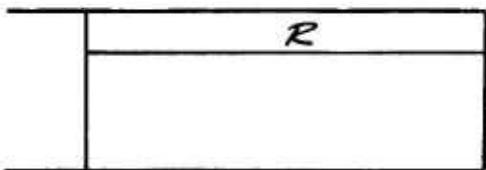

The empty wing moment of inertia is approximately one seventh of the fully loaded value. The aerodynamic forces are thus much greater in relation to the inertia forces when the system is at the

## INTRODUCTION (Continued)

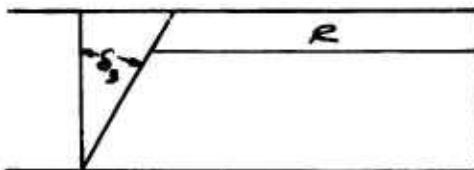

minimum flying weight. The problem is to select suitable wing damping and aerodynamic stiffness so that wing deflections do not at any time exceed 15 degrees. Upward deflections are critical, from considerations of rotor clearance, but aside from this, the problems of designing the hinge and the associated connections increase as increasingly larger deflections are permitted. Two simple methods of stabilizing and controlling the floating wing are available:

### 1. Skewed Hinge

The hinge lies along some line skewed relative to the chord, in such a manner that as the wing floats up, the angle of attack is reduced, thus providing restoring moments. The disadvantage of this method is that the aerodynamic damping about the hinge is reduced as the stiffness increases, as shown below:

Effective flapping  
radius = R

Effective flapping  
radius =  $R \cos \delta_s$

### 2. Geared Trailing Edge Flaps

The flaps are mechanically linked to the wing to move as a function of wing flapping angle. By the use of differentially geared flaps (i.e. outboard flaps moving up, inboard down, as the wing flaps up) and the judicious selection of gear ratio, a wide range of aerodynamic

## INTRODUCTION (Continued)

stiffness can be obtained, together with some degree of control over the resultant shear loads at the hinge. Further, there is no loss of damping about the wing hinge by this method.

### CONTROL:

The rolling moment of inertia of a helicopter is usually low, but with the addition of large span wings, each holding 7000 pounds of fuel, it becomes large, and the roll control power suffers accordingly. To supplement it, it is proposed to use the flap panels as ailerons, in addition to their function of stabilizing the wing. By the use of differential collective pitch, the tandem rotor helicopter has more than adequate pitch control, and it is not anticipated that control of this mode will present any serious problems as a helicopter. The H-21 is deficient in yaw control sensitivity. Addition of the floating fuel wing will reduce control sensitivity by a factor of five. However, this is not expected to be a problem, as the floating wing system is not capable of hovering and very low speed flight, which is the regime where the H-21 yaw control deficiency is experienced.

### PERFORMANCE:

The location of the wing is a compromise between the conflicting requirements of performance and stability. To obtain optimum range, the wing should be located as far forward as possible, to minimize interference drag and the rearward inclination of the lift vector produced by the rotor downwash field. For the same reason, to obtain shortest take-off distances, the wing should be located forward. Because of the much increased maximum weight, take-off will be power limited, and range suffers on two counts if the wing is not located at the optimum forward position. On the other hand, longitudinal stability requires that the wing be located at or near the basic helicopter cg.

## LONGITUDINAL ANALYSIS

### DERIVATION OF EQUATIONS:

The system being analyzed is one of a very complex nature. The maximum mass ratio of the flapping fuel wing to that of the helicopter is 1.44 to 1. This will give rise to important inertial coupling terms. The Lagrange Equation of Motion for generalized coordinates is a completely rigorous analysis which is well suited to the solution of this type of problem.

The Lagrange Equation yields all the mass and inertial terms (Ref. App. (A)) which must be equated to the external forces acting on the system. The forces include aerodynamic forces acting on the rotors, fuselage and the flapping wings. Those forces acting on the rotor and fuselage were obtained from existing helicopter stability analyses. The aerodynamic forces exerted on the wing were derived by the principal of virtual work (Ref. App. (A)).

Two different types of wing stabilization systems were investigated (i.e.  $\delta_f$ , hinge and differentially geared trailing edge flaps). Each wing was considered to be composed of two separate spanwise sections, the section span corresponding to the differential flap span. The lift and drag were computed for each section so that changes in aerodynamic forces on the wing could be readily calculated for differential flap deflection. The lift distribution for the inboard section was assumed to be rectangular while that for the outboard section was assumed to be elliptic. The final equations shown in Appendix (A) are completely general and apply to both stability systems.

### Assumptions:

1. Since the mass properties and aerodynamic characteristics of each wing are similar, then the flapping motions will be identical and one equation will describe the motion.
2. Small angle assumptions and linearization are applied only to the final set of equations.
3. Initial pitch angle ( $\theta_{H_0}$ ) and wing flap angle ( $\beta_{H_0}$ ) are assumed to be small and are excluded from the analysis.

## LONGITUDINAL ANALYSIS (Continued)

### ANALYTIC SOLUTION OF EQUATIONS:

A very effective engineering tool is the root solution of the characteristic equation. The roots not only yield periods and time to double or half amplitudes but serve as a cross check for analog time histories.

Given a set of four linear simultaneous differential equations in four unknowns, the solution thereof is accomplished by arranging the coefficients of the variables into a fourth order determinant having quadratic elements. Expansion of the determinant yields a sixth order polynomial which is then solved for the roots.

In order to determine trends for several configurations, the roots of the corresponding characteristic equations can be presented on root locus plots (Ref. Appendix (B)), where horizontal lines indicate constant frequency and vertical lines indicate time to half or double amplitude. The roots may indicate four types of response:

1. Complex roots where the sign of the real part is positive indicate a divergent oscillation ( $A \pm Bi$ ).
2. Complex roots where the sign of the real part is negative indicate a damped oscillation ( $-A \pm Bi$ ).
3. A positive real root indicates a non-oscillatory divergence.
4. A negative real root indicates a non-oscillatory convergence.

### RESULTS OF LONGITUDINAL ANALYSIS:

Throughout the longitudinal investigation, all cases were judged on the basis of the system response to a 30 ft/sec (fps) vertical gust, and the stability characteristics compared with those of the basic helicopter.

The results of the analysis indicate that to satisfy stability criteria, a zero  $\delta$ , hinged wing stabilized with differential trailing edge flaps set at a  $\pm 2$  deg/deg gearing ratio, must be

## LONGITUDINAL ANALYSIS (Continued)

located directly beneath the basic helicopter cg. Cases 21 and 26 are the light and heavy wing cases corresponding to the above description.

With the wing located in this position, flap gearing ratios of  $\pm 3$  and  $\pm 1$  (Cases 25 and 27 - heavy wing, Cases 20 and 22 - light wing) were also investigated. Examination of the three light wing configurations shows all cases exhibit highly damped oscillations. The roots of the characteristic equations as well as analog time histories indicate minor variations in both period and damping. Similar responses exhibited are high frequency wing modes (avg. period = 1.5 sec) damped to half amplitude in .39 seconds, superimposed on a long period (23 sec) mode. This long period is common to both wing and pitch responses. Both angles are comparatively small.

In order to avoid wing-rotor interference, wing flap angles must be .25 radian or less; therefore, this criterion becomes critical with the light wing configuration. Intuitive reasoning suggests that in response to a 30 ft/sec vertical gust, the empty fuel wings will immediately flap up. This is found to be true by the following analytical study.

If the system is disturbed by a 30 ft/sec vertical gust, the vertical accelerations of the helicopter and the wing viewed separately may be calculated as follows:

$$(\Delta\alpha) = .222 \text{ rad}$$

$$(\zeta_\alpha)_{\text{hel}} = -33000 \text{ lb/rad}$$

$$(\zeta_\alpha)_{\text{wing}} = -46000 \text{ lb/rad}$$

Therefore, the resulting forces will be:

$$\zeta_{\text{hel}} = -7300 \text{ pounds}$$

$$\zeta_{\text{wing}} = -10200 \text{ pounds}$$

$$\text{Mass}_{\text{hel}} = 344.7 \text{ slugs}$$

## LONGITUDINAL ANALYSIS (Continued)

Masswings = 497 slugs (heavy) and 62 slugs (light)

$$\text{Hel.Acc.} = \frac{7300}{344.7} = 2.12 \text{ ft/sec}^2$$

$$\text{Wing Acc. (heavy)} = \frac{10200}{497} = 20.5 \text{ ft/sec}^2$$

Since both initial accelerations of the wing and helicopter are nearly equal, initial down wing flap angles should be small. However:

$$\text{Wing Acc. (light)} = \frac{10200}{62} = 165 \text{ ft/sec}^2$$

With the high accelerations of the empty wing compared to those of the helicopter, it is probable that large initial wing flap angles will result.

Based on this wing-rotor interference criterion, the minimum gearing ratio is  $\pm 2$  deg/deg which shows an initial flapping excursion of .25 radians.

Examination of Cases 25, 26 and 27 shows, again, very little change in either period or damping between all three cases. Wing flap angles are small (less than .1 rad) and mildly divergent. Pitch angles are fairly large with 12 second periods and double amplitude in 6.4 seconds. Maximum amplitude after four seconds is .5 radian. However, sufficient control power is available to make the system flyable.

Both the  $\delta_3$  hinged wing and the differential trailing edge geared flap wing located in the forward position (wing a.c. 14 ft fwd of hel. cg.) were analyzed and found to be not feasible. Looking at the two configurations individually, the  $\delta_3$  hinged system exhibited static lateral instability. The longitudinal response of the hinge indicated dynamic instability with a 16.6 second period and doubled amplitude in 2.5 seconds.

The effect of increasing the spring stiffness (zero  $\delta_3 \rightarrow 45^\circ \delta_3$ ) resulted in increasing the period and decreasing the time to double amplitude. Thus the configuration approaches that of a fixed wing aircraft with the wing located far forward of the cg. The disadvantage of the skewed hinge lies in the adverse effects on the wing root shear loads. For example, as the helicopter pitches nose

## LONGITUDINAL ANALYSIS (Continued)

up in response to a vertical gust, the heavy wing initially flaps downward, thus increasing the angle of attack. This results in a net up shear load at the hinge which increases the nose up pitching moments and tends to pitch the aircraft more nose up.

The alternative wing stabilization system (differentially geared flaps) was investigated with the wing located in the same forward position.

The system response to a 30 fps gust indicates that a gearing ratio of 1 deg/deg yields an aerodynamic spring with sufficient stiffness to keep wing flapping excursions acceptably small. However, large pitching motions are also recorded. (See Figure 7)

With fully loaded fuel tanks, the system appeared to be acceptable both longitudinally and from a lateral-directional standpoint. For this configuration, the empty tanks case exhibited longitudinal static instability with .75 second to double amplitude.

Comparison of the incremental lift acting on the fuel wing with full and empty tanks shows that in response to a 30 fps gust, the increment in lift is 70% of the steady lift for the fully loaded wing and 500% of the steady lift for the empty wing. Therefore, initial wing flap angles and accelerations are quite large for the empty wing case. This effect, coupled with the fact that the pitch inertia of the system is reduced by a factor of 2, induces high pitch accelerations which destabilize the system.

In summary, longitudinal stability characteristics dictate that the fuel wing be hinged with zero  $\delta_3$ , directly beneath the helicopter cg using a flap gearing ratio of  $\pm 2$  deg/deg.

## LATERAL-DIRECTIONAL ANALYSIS

### DERIVATION OF EQUATIONS:

The application of Lagrange's Equations to the lateral-directional mode is prohibitively long and laborious, approximately four times as much work being required as compared with the longitudinal case. Consequently, a simpler and less time-consuming method, yielding acceptable accuracy, was used. The method is based on an initial assumption of small perturbations and the existence of the following four modes:

1. Roll of the system treated as a rigid body about the compound center-of-gravity.
2. Rigid yaw of the system about the compound center-of-gravity.
3. Rigid lateral translation of the system.
4. Flapping of the wing about the hinge.

Linearized expressions, in terms of small disturbances in the roll, yaw, sideslip and flapping modes, which were derived, enabled the calculation of lift, drag and pitching moment to be made at a general spanwise wing station. The forces and moments, when integrated over the span, yield the conventional fixed wing lateral and directional aerodynamic stability derivatives, and, in addition, include the effect of the flapping freedom on the aircraft motion.

### Assumptions:

To keep the equations of motion and the calculation of the stability derivatives from becoming too lengthy, the following assumptions were considered justified:

1. The motion is anti-symmetric about the aircraft plane of symmetry.
2. The initial flapping angle is zero.
3. The angle between the aircraft principal axis and the flight path is small.

## LATERAL-DIRECTIONAL ANALYSIS (Continued)

The first two assumptions exclude the possibility of investigating the non-linear dihedral effect that occurs in a sideslip when the initial flapping angle is not zero. It is considered that this is potentially the most restrictive assumption in this analysis, and that in any refinement of the method, it should be eliminated.

The inertial terms, forming the left hand side of the final equations of motion form a symmetric matrix, from which the product of inertia terms are excluded by Assumption 3.

### Fuselage, Tail and Rotor Contributions to Stability:

The basic helicopter contributions to the stability derivatives were obtained from:

1. Flight test and wind tunnel (for the fuselage and tail).
2. Rigid rotor stability analysis.

### Representation of Geared Flap:

The assumption was made that the geared flap contributes only to the aerodynamic spring stiffness and makes no contribution to aerodynamic damping. The effect of the flap can, therefore, be represented by:

1. A change in the effective lift curve slope.
2. An increment in the section drag coefficient, varying linearly with the wing flapping angle.
3. An increment in the section pitching moment coefficient, varying linearly with the wing flapping angle.

### Displacement Equations:

A right-handed axis system is used, having the origin at the compound cg, with the X axis positive forward, the Y axis positive to the right and the Z axis positive down. Positive rotations are clockwise when looking in the positive directions. Positive wing flapping is right wing down, i.e., in the same sense as positive

## LATERAL-DIRECTIONAL ANALYSIS (Continued)

roll. Since the motion is assumed to be anti-symmetric, only the right half of the helicopter plus wing need be considered.

### RESULTS OF LATERAL-DIRECTIONAL ANALYSIS:

The time histories for Cases 12 and 1 (Figure 17-18), and others unpublished, indicate that the response in roll to a side gust becomes more divergent as  $\delta_3$  is increased. This is borne out by the lateral-directional stability roots in Table 27. For zero the unstable oscillation has a period of 12.2 seconds, and takes 6.3 seconds to double amplitude. When  $\delta_3$  is increased to 45°, the period is reduced to 10.5 seconds and the time to double amplitude is now only 2.4 seconds. This divergence is the basis of the choice of zero  $\delta_3$ , and as the loss of damping resulting from skewing the hinge is so large, (it varies as the cosine of  $\delta_3$ ), it was not considered fruitful to pursue this approach when the geared flap provides such a powerful aerodynamic spring.

The selection of fore-and-aft location is primarily dictated by the requirements of performance and longitudinal stability, since it is of relatively little importance to the lateral-directional stability - Cases 4 and 27 illustrate the effect of moving the wing aft at maximum weight, and Cases 18 and 22 show the effect for the empty wing cases. At neither weight is there any significant change in the motion. For the heavy wing (4 and 27, flap gearing  $\pm 1$ ), the only changes appear in the second and third roots (Table 27). The slowly divergent second root in Case 4 becomes very lightly damped, i.e., essentially neutral stability. The very lightly damped long period oscillation corresponding to the third root becomes slowly divergent (27 seconds to double amplitude) and the period increases from 12.5 to 15.8 seconds. Examination of the analog traces for these cases shows that the effect of the changes in the roots is small.

At the light weight (Cases 18 and 22), the changes resulting from moving the wing aft are still less marked - only the third root shows any changes worth commenting on. The subsidence corresponding to this root becomes more rapid - taking 23 seconds to half amplitude, compared with 33.0 seconds with the wing in the forward position. One other point worth mentioning is that the initial swing of  $\alpha$  is approximately halved -2.0° for Case 22, compared with 3.4° for Case 18.

LATERAL-DIRECTIONAL ANALYSIS (Continued)

Selection of Flap Gearing:

The differentially geared flap is a powerful method of modifying the aerodynamic spring stiffness and resultant shear loads at the hinge, without sacrificing the damping. When the wing flaps up, the outboard section of the flap deflects up, providing the aerodynamic stiffness, while the inboard section deflects downwards, countering the downward shear loads generated by the upward deflected outboard flap. This increment in the net shear provides a stabilizing rolling moment on the helicopter.

Expressed in another way, consider the helicopter in steady level flight, with the wings in the neutral position. Let a disturbance induce a rolling velocity to the right. Due to its own inertia the right wing cg will tend to stay in the same vertical location, which means that the wing relative to the helicopter will flap up. The outboard flap panel will deflect up, inducing a downward flapping hinge moment, and shear force increasing the rate of roll. The inboard flap panel will deflect downwards, inducing a shear force that reduces the rate of roll. It will at the same time slightly reduce the aerodynamic stiffness, but as it acts much closer to the wing hinge than the outboard section, it is much less powerful in influencing stiffness than in modifying the shear loads.

The gearing ratio chosen (defined as flap deflection per unit wing deflection) should be as low as possible consistent with acceptable stability, as the lift generated by flap deflection rapidly becomes non-linear. The flap is also required as a high-lift device at least in the early stages of a ferry flight, and the outboard panels at least will be required to serve as roll control.

The investigation into flap gearing ratio is covered in Cases 20, 21 and 22 (light wing) and 25, 26 and 27 (heavy). In all cases, the inboard and outboard sections move differentially, at gear ratios 1, 2 and 3. Examination of the roots and analog traces leads us to conclude that there is little to be gained by increasing the flap gearing ratio beyond  $\pm 1$ . Taking the light wing first, we note that as the flap gearing is increased from 1 to 3, the oscillatory part of the first root remains virtually constant, while the time to halve amplitude increases from 8.0 to 9.0 seconds. The only other root affected

LATERAL-DIRECTIONAL ANALYSIS (Continued)

is the other oscillatory root, representing a very fast highly damped mode. The period is reduced from 1.5 seconds to .7 second, and the time to halve amplitude goes from .32 to .27 seconds.

Similarly, with the heavy wing (25, 26 and 27), only the oscillatory roots are influenced by the gearing. The long period oscillation is mildly divergent, becoming more so as the gearing is increased (21 seconds to double amplitude at the  $\pm 3$  gearing, 29 seconds for  $\pm 1$ ) and the period remains virtually unchanged. The short period highly damped oscillation changes noticeably in period - going from 3.48 seconds to 1.93 seconds, and the time to halve amplitude remains nearly unchanged at 1.6 seconds.

In summary, the straight hinge was chosen because of the rapid divergence that a skewed hinge produced. The fore and aft position is relatively unimportant to the lateral-directional stability, and on the basis of cases 20-27, there is little to be gained by increasing the flap gearing ratio beyond  $\pm 1$  per unit wing deflection.

## FLIGHT SIMULATOR STUDY

The investigation up to this point was concerned primarily with obtaining a wing-helicopter configuration that would satisfy stability criteria. Cases 21 and 26 fulfill this requirement. However, high roll inertia of the system reduces the lateral control sensitivity by a factor of fifty as compared to the basic helicopter; in order to bring roll control up to an acceptable level, additional means of control power in the form of ailerons are considered necessary. To aid in evaluating the control effectiveness, flight simulator studies were made to compare lateral-directional control of the basic helicopter with that of the wing-helicopter combination with and without aileron control.

The simulator used in this analysis consists of a mock-up of approximately one half of the YHC-1A cockpit area. Forward visibility through the windshield is approximately the same as it is in the YHC-1A aircraft. Adjustable control throw stops, friction, and force gradients are provided. Aircraft flight information is presented in two ways.

1. Voltmeters with modified instrument faces (airspeed, rate of climb, etc.) have been inserted in place of true aircraft instruments. These meters are arranged in their proper location on an instrument panel mockup.
2. A servo-driven color transparency is projected on a screen covering the pilot's entire forward windshield field of vision. This image, which represents the horizon and ground orientation, moves in response to computer signals, and imparts roll, pitch and yawing motion information to the pilot.

The flight program was set up as follows:

The test pilot flew a simulated H-21 helicopter to familiarize himself with the simulator and to give himself a base case with which to compare the wing-helicopter combination. Except for the fact that the controls seemed a bit too sensitive to the pilot, simulator response compared favorably with actual helicopter characteristics. The original intent in evaluating the wing-helicopter combination was to fly the longitudinal case and lateral case separately and once the pilot familiarized himself with each mode,

FLIGHT SIMULATOR STUDY (Continued)

he would be presented with the coupled longitudinal lateral system. However, it was found that the longitudinal mode was very simple to fly but the slide presentation was very poor (jerky motion) such that when both modes were coupled, the system required too much concentration on the pilot's part to yield any useful information. Therefore, roll yaw characteristics and longitudinal characteristics were evaluated separately.

Test pilot comments indicate that the floating wing-helicopter system without aileron control is much more stable than the basic helicopter. However, as expected, roll control was noticeably more sluggish. Recovery from bank angles of 20 degrees or less was possible in both smooth and turbulent air (max  $\pm 10$  fps gust peaks). Yaw control was adequate, but adverse roll effects due to pedal displacement were not noticeable. Two and one half ( $2\frac{1}{2}$ ) degrees of aileron per inch of stick improved the roll control considerably. (This aileron gearing increases control power by 80%.)

Small-amplitude short-period oscillations were observed in both the  $2\frac{1}{2}^{\circ}$  and  $5^{\circ}$  aileron cases. Only those of the  $5^{\circ}$  case had amplitudes large enough to be annoying to the pilot. Adequate directional control was available in both cases, although adverse roll effects were still present. Although the  $5^{\circ}$  case compares favorably with the basic helicopter with regard to roll response, the  $2\frac{1}{2}^{\circ}$  case was considered to be an acceptable compromise since wing flap angles are small. It is also desirable to keep aileron deflections small, for the aileron is used simultaneously as a flap and as a wing stabilization system.

Lateral stick step response is shown in Figure 27 with  $5^{\circ}$  of aileron/in to show the effect of increased control power.

## PERFORMANCE ANALYSIS

### CRUISE:

The method of analysis used to calculate the range of the helicopter-wing configuration involved the modification of longitudinal trim equations for the standard helicopter. This analysis, programmed on a digital computer, iteratively determines the longitudinal characteristics of several helicopter-wing configurations at various equilibrium conditions. The basic helicopter trim analysis was modified by accounting for the interference of the wing on the rear rotor and calculating an equivalent flat plate area based on the following items:

1. Induced drag of the wing determined by  $C_L$ ;
2. Interference of front rotor on the wing in terms of a corrected induced angle;
3. Profile drag of the wing including the landing gear;
4. Profile drag of the flap.

By varying the profile drag of the flaps, which is related directly to flap deflection at different wing lifts, the helicopter water-line angle of attack was determined, as shown in Figures 30 through 38. (NOTE: All figures are located in Appendix C). The wing trim angle of attack was calculated by using Figure 39 (lift coefficient versus angle of attack). The difference between the helicopter waterline and wing angle represents the required wing incidence for a given flap deflection. Figures 40, 41 and 42 present power required and Figure 43 gives the fuel flow as a function of horsepower.

The following sample problem is presented in order to clarify the procedure used in the performance analysis:

Given:

wing incidence ( $i_w$ )	= 8.5°
wing lift	= 16,000 lb
forward speed	= 80 knots

## PERFORMANCE ANALYSIS (Continued)

Enter Figure 37 and find point where the delta angle between wing and waterline is  $8.5^\circ$  at minimum flap deflection.

$$\text{Flap deflection } (\alpha_f) = 15^\circ$$

$$\text{Wing angle of attack } (\alpha_w) = 5.0^\circ$$

$$\begin{aligned} \text{Waterline angle of attack} \\ (\alpha_{WL}) &= -3.5^\circ \end{aligned}$$

For a given flap deflection of  $15^\circ$  at 80 knots, Figure 42 yields horsepower required of 1240 hp and fuel flow for this sample is 950 lb/hr (Figure 43). The miles per pound of fuel is calculated by dividing the forward speed by the fuel flow which, for this case, is .0842 miles per pound.

### TAKE-OFF:

There are two types of take-off procedures which were considered. The first method is to accelerate the system down the runway at a trim attitude associated with the take-off speed and when the take-off speed is reached, the system will break ground. The second method incorporates the procedure where the helicopter's attitude is such that the maximum accelerating force is in the horizontal direction. When the take-off speed is reached, the helicopter-wing configuration is rotated to the trim angle and the system takes off.

The "Hartman's Analysis" was used to calculate the break ground distance. The following equation was solved graphically and the distance required to break ground was obtained.

$$S = \frac{1}{2} \int_0^{V_{TO}} \frac{d(V)}{\alpha}$$

The distances to climb to 50 ft is dependent upon the available excess power during climb. The distance to make a steady climb

## PERFORMANCE ANALYSIS (Continued)

from ground to 50 ft is added directly to the ground run to obtain the total distance over a 50 ft obstacle.

### RESULTS OF PERFORMANCE STUDY:

The all-out range was the primary area of investigation based on the new wing configuration. The take-off distances and control positions are also studied to insure that the wing fuel tank does not restrict the helicopter's operation throughout the entire flight.

The method used in calculating the miles per pound of fuel is described in the performance analysis section. Tables 29, 30 and 31 present for a variable wing incidence the flight characteristics for various wing lifts, forward speeds, and rpm's for the wing in the forward position. The criterion for choosing a given trim condition is maximum miles per pound of fuel. Figure 44 presents a ferry range of 2400 n.mi. using the forward positioned wing with a variable incidence. If a range of only 2000 n. mi. is desired, the aircraft could take-off at a wing weight of 12,100 pounds.

A constant wing incidence is desirable from a design aspect. In studying the effect it might have on range, a wing incidence of  $8.5^\circ$  was selected from take-off considerations and was held constant throughout the regime. The same method of calculation and presentation was performed on the constant wing incidence with the wing in the forward position. Table 32 presents the various characteristics. Note that the flap deflection changes with rpm at constant wing incidence.

Figure 45 presents the all-out range of 2205 n. mi. for the constant wing incidence configuration. The take-off wing gross weight of 13,700 pounds is also shown for a range of 2000 n. mi.

Figures 46 and 47 show the range of the variable and constant wing incidence if an additional profile drag increment is arbitrarily added to the drag calculated with the wing in the forward position. The flight schedule for the all-out range mission for both variable and constant wing incidence is presented in Figures 48 and 49.

The location of the wing on the helicopter has an effect on the range. If the wing is moved to the most aft position, that is, under the rear door, the front rotor's induced angle effect on the wing is increased threefold and its related effect on range is shown in

## PERFORMANCE ANALYSIS (Continued)

Figures 50 and 51. The results yield an all-out range of 1975 n.mi. for a variable wing incidence and 1765 n.mi. for the constant wing incidence. The take-off wing gross weight is reduced to 14,800 pounds and 14,200 pounds respectively because of power limitations.

The new range as affected by wing position is computed by determining the power required for the drag increase. The optimum miles per pound for the aft wing position is calculated at the same forward speed as that of the forward wing position since the drag increase due to moving the wing to the most aft position is independent of the forward speed. The helicopter trim angles will not change appreciably. Because of power limits at 2300 engine rpm for the 9000 pound lift condition, the engine speed had to be increased to 2500 rpm for the aft wing position. The horsepowers presented in Figure 52 (variable wing incidence) and Figure 53 (constant wing incidence) show the comparison between the two configurations. The configuration with the wing in the most aft wing position reaches a power limit at wing gross weights less than maximum; hence, an additional range penalty must be paid because the helicopter-wing configuration cannot take off at a maximum gross weight of 16000 pounds. Table 33 presents the range for the various configurations and their associated maximum take-off gross weights.

The control parameters for the forward wing configuration were studied to insure that the control margins were adequate. The investigation analyzing the effect of moving the wing to the aft position indicated that the control positions will not change appreciably from those calculated for the wing in the forward position. Figure 54 presents the required longitudinal cyclic pitch versus fuel weight for both variable and constant wing incidence. Collective pitch margin was sufficient for both configurations as shown in Figures 55 and 56.

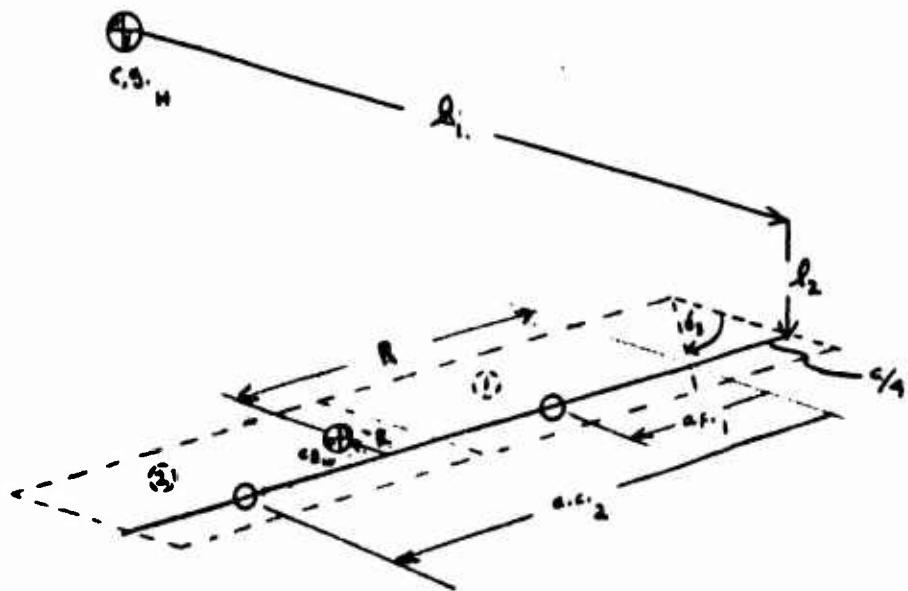

The procedure of obtaining take-off distances was discussed in the "Method of Investigation" section. Table 34 presents a summary of take-off procedures and results.

EQUATIONS OF MOTION**

**FIG. 1**

**FIG. 2      SIGN CONVENTION**

## DIFFERENTIALLY GEARED FLAPS

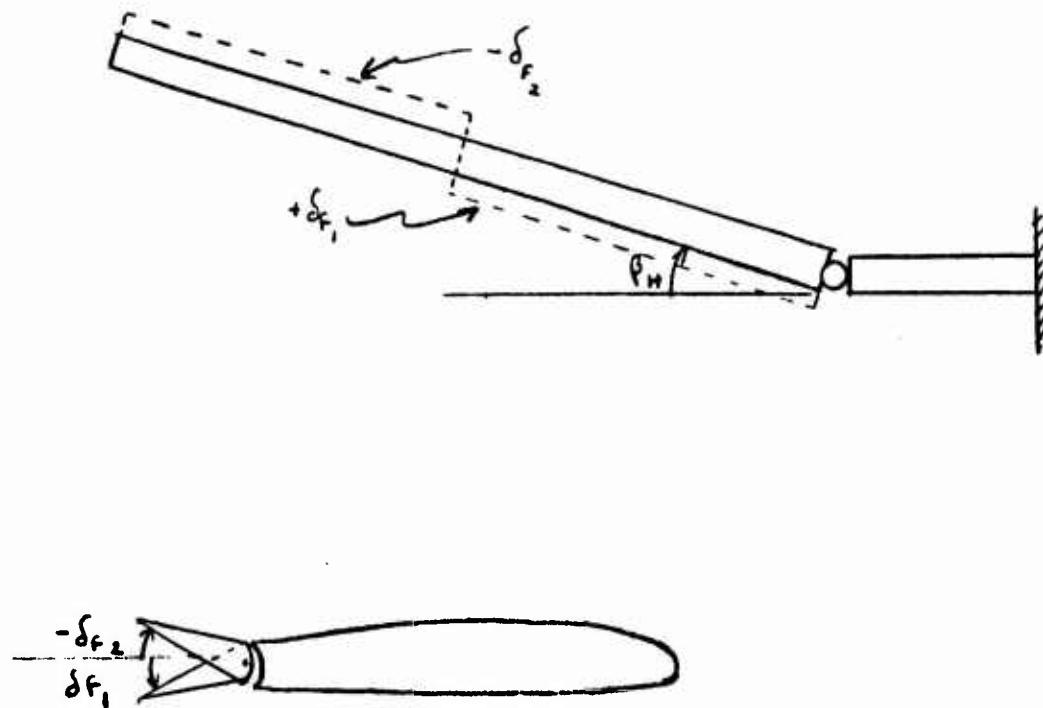

FIG. 3

The Lagrange equations of motion for generalized coordinates is stated as follows:

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}} \right) - \frac{\partial T}{\partial q} + \frac{\partial V}{\partial q} = Q_q$$

Where:

- $T$  Total Kinetic Energy of the system
- $V$  Total Potential Energy of the system
- $q$  Generalized Coordinate
- $Q_q$  Virtual Work Terms

The four generalized coordinates of this system are:

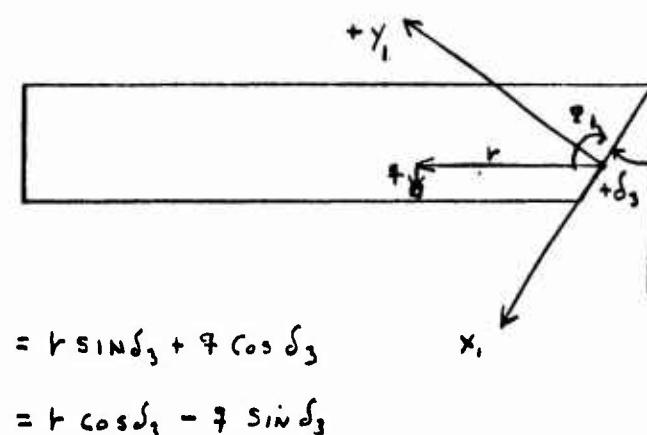

- $\Theta$  Helicopter Pitch Angle
- $\theta_w$  Wing Flapping Angle referred to the hinge
- $x$  Longitudinal displacement from a fixed earth reference point.

Z

Vertical displacement from a fixed earth reference point.

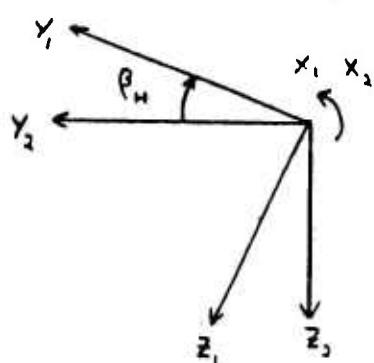

In order to determine the total kinetic and potential energy of the system, it is necessary to obtain the displacement of all component parts with respect to some reference point. In this case all motion is referred to primary inertial earth fixed axes.

Starting with axes fixed to the right wing as shown below:

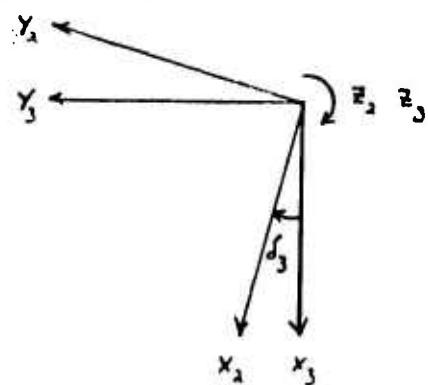

The total displacement vector is obtained by rotating and translating axes back to the fixed axis system as follows.

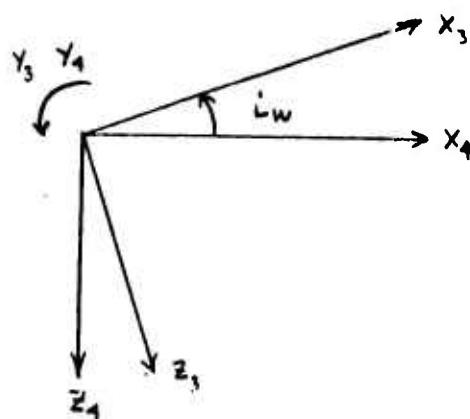

(1) Rotation through  $\beta_H$

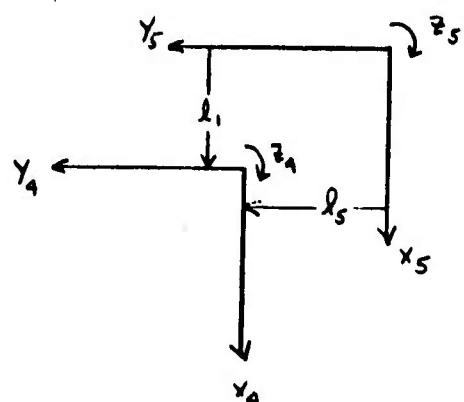

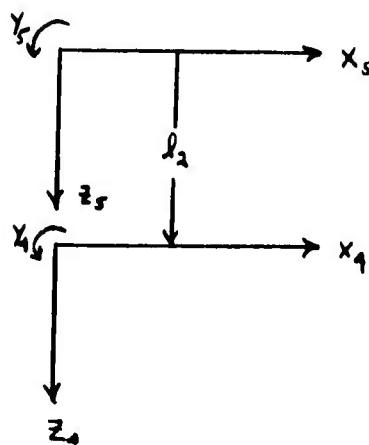

(2) Rotation through  $S_3$

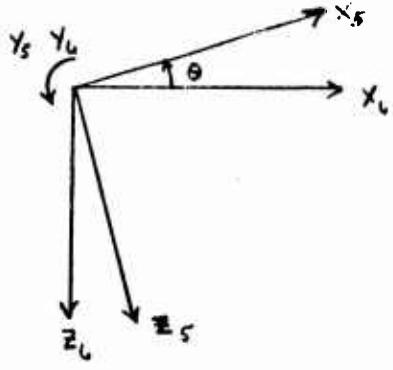

(3) Rotation through  $L_w$

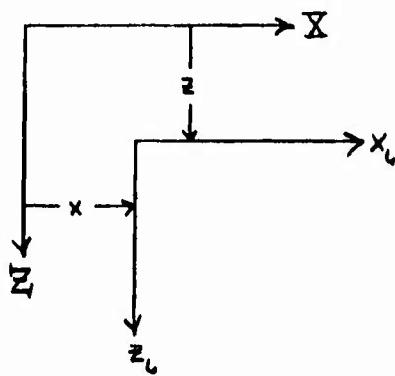

(4) Translation to Helicopter c.g.

(5) Rotation through  $\theta$

(6) Translation through  $x$  &  $z$

The final components of the displacement vector of any particle on the right wing are:

$$\begin{aligned}
 X = & x + x_1 \cos \delta_3 \cos i_w \cos \theta - y_1 \cos \beta_u \sin \delta_3 \cos i_w \cos \theta \\
 & - y_1 \sin \beta_u \sin i_w \cos \theta + l_1 \cos \theta - y_1 \sin \beta_u \cos i_w \sin \theta \\
 & - x_1 \cos \delta_3 \sin i_w \sin \theta + y_1 \cos \beta_u \sin \delta_3 \sin i_w \sin \theta \\
 & + l_2 \sin \theta
 \end{aligned}$$

$$Y = y_1 \cos \beta_u \cos \delta_3 + x_1 \sin \delta_3 + l_5$$

$$\begin{aligned}
Z &= z - Y_1 \sin \beta_H \cos i_w \cos \theta - X_1 \cos \delta_3 \sin i_w \cos \theta \\
&\quad + Y_1 \cos \beta_H \sin \delta_3 \sin i_w \cos \theta + l_2 \cos \theta - l_1 \sin \theta \\
&\quad - X_1 \cos \delta_3 \cos i_w \sin \theta + Y_1 \cos \beta_H \sin \delta_3 \cos i_w \sin \theta \\
&\quad + Y_1 \sin \beta_H \sin i_w \sin \theta
\end{aligned}$$

Appropriate substitution of the following variables yields the components of the displacement vector for the left wing.

$$\beta_{H_R} = -\beta_{H_L}$$

$$\delta_{3R} = -\delta_{3L}$$

$$X_R = X_L$$

$$Y_R = -Y_L$$

$$Z_R = Z_L$$

Calculating the kinetic and potential energy as follows -

$$T = \frac{1}{2} \int (\dot{X}^2 + \dot{Y}^2 + \dot{Z}^2) dm$$

$$V = \int (-Z) g dm$$

Applying the Lagrange equation yields  
the following four equations of motion

$$EQ(1) \quad A_1 \ddot{\theta} + A_2 \dot{\theta} + A_3 \ddot{z} + A_4 \ddot{x} + A_5 \ddot{\beta}_n + A_6 \dot{\beta}_n = Q_\theta$$

$$EQ(2) \quad B_1 \ddot{\theta} + B_2 \dot{\theta} + B_3 \ddot{z} + B_4 \ddot{x} + B_5 \ddot{\beta}_n + B_6 \dot{\beta}_n = Q_{\beta_n}$$

$$EQ(3) \quad C_1 \ddot{\theta} + C_2 \ddot{x} + C_3 \ddot{\beta}_n = Q_x$$

$$EQ(4) \quad D_1 \ddot{\theta} + D_2 \ddot{z} + D_3 \ddot{\beta}_n = Q_z$$

Where:

$$A_1 = I_{y_n} + I_1 \sin^2 \alpha \delta_3 \cos^2 \omega + 2 I_2 (\sin^4 \delta_3 + \cos^4 \delta_3)$$

$$+ 4 I_3 \cos^3 \delta_3 \sin \delta_3 \cos^3 \omega + 2 M_w (\ell_1^2 + \ell_2^2)$$

$$- 4 I_3 \sin^3 \delta_3 \cos \delta_3 \cos^3 \omega - 4 \sigma_2 \ell_2 \sin \omega$$

$$+ I_2 \sin^2 \alpha \delta_3 \sin^2 \omega + 2 \sigma_1 \ell_1 \sin 2 \delta_3 \cos \omega$$

$$+ 4 \sigma_2 \ell_1 \cos^2 \delta_3 \cos \omega$$

$$A_2 = 2g [\ell_2 M_w - \sigma_2 \sin \omega]$$

$$A_3 = -2 \left[ l_1 M_w - \sigma_2 \cos i_w \right]$$

$$A_4 = 2 \left[ l_2 M_w - \sigma_2 \sin i_w \right]$$

$$\begin{aligned} A_5 = 2 & \left[ I_3 \cos \delta_3 - I_2 \sin \delta_3 - \sigma_1 l_2 \cos \delta_3 \sin i_w \right. \\ & + \sigma_2 l_2 \sin \delta_3 \sin i_w + \sigma_1 l_1 \cos \delta_3 \cos i_w \\ & \left. - \sigma_2 l_1 \sin \delta_3 \cos i_w \right] \end{aligned}$$

$$A_6 = 2g \sin i_w \left[ \sigma_2 \sin \delta_3 - \sigma_1 \cos \delta_3 \right]$$

$$\begin{aligned} B_1 = 2 & \left[ I_3 \cos \delta_3 - I_2 \sin \delta_3 + \sigma_1 \cos \delta_3 (l_1 \cos i_w - l_2 \sin i_w) \right. \\ & \left. + \sigma_2 \sin \delta_3 (l_2 \sin i_w - l_1 \cos i_w) \right] \end{aligned}$$

$$B_2 = 2g \sin i_w \left[ \sigma_2 \sin \delta_3 - \sigma_1 \cos \delta_3 \right]$$

$$B_3 = 2 \cos i_w \left[ \sigma_2 \sin \delta_3 - \sigma_1 \cos \delta_3 \right]$$

$$B_4 = 2 \sin i_w \left[ \sigma_2 \sin \delta_3 - \sigma_1 \cos \delta_3 \right]$$

$$B_5 = 2 \left[ I_1 \cos^2 \delta_3 + I_2 \sin^2 \delta_3 - I_3 \sin 2\delta_3 \right]$$

$$B_6 = 2g \sin \delta_3 \sin \omega \left[ \sigma_1 \cos \delta_3 - \sigma_2 \sin \delta_3 \right]$$

$$C_1 = 2 \left[ l_2 M_w - \sigma_2 \sin \omega \right]$$

$$C_2 = -M_H + 2M_w$$

$$C_3 = 2 \sin \omega \left[ \sigma_2 \sin \delta_3 - \sigma_1 \cos \delta_3 \right]$$

$$D_1 = -2 \left[ l_1 M_w + \sigma_2 \cos \omega \right]$$

$$D_2 = M_H + 2M_w$$

$$D_3 = -2 \cos \omega \left[ \sigma_2 \sin \delta_3 + \sigma_1 \cos \delta_3 \right]$$

The inertial part of the equations of motion as presented must now be equated to the external forces acting on the system (  $Q_q$  ). This is accomplished by:

- (1) Calculating rotor and fuselage derivatives.
- (2) Aerodynamic forces on the wing were derived by the principal of virtual work outlined as follows:

$$Q_q = \frac{\partial W}{\partial q}$$

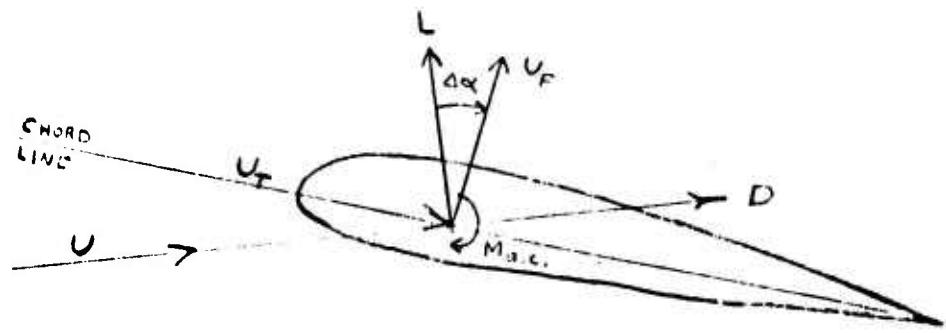

Where  $W = \sum F \delta s + \sum M \delta \varphi$

$F \sim$  Constant Force

$\delta s$  Virtual Linear Displacement

$M$  Constant Moment

$\delta \varphi$  Virtual Angular Displacement

$$F_x = D \cos \Delta\alpha - L \sin \Delta\alpha$$

$$F_z = L \cos \Delta\alpha + D \sin \Delta\alpha$$

$$M = M_{a.c.}$$

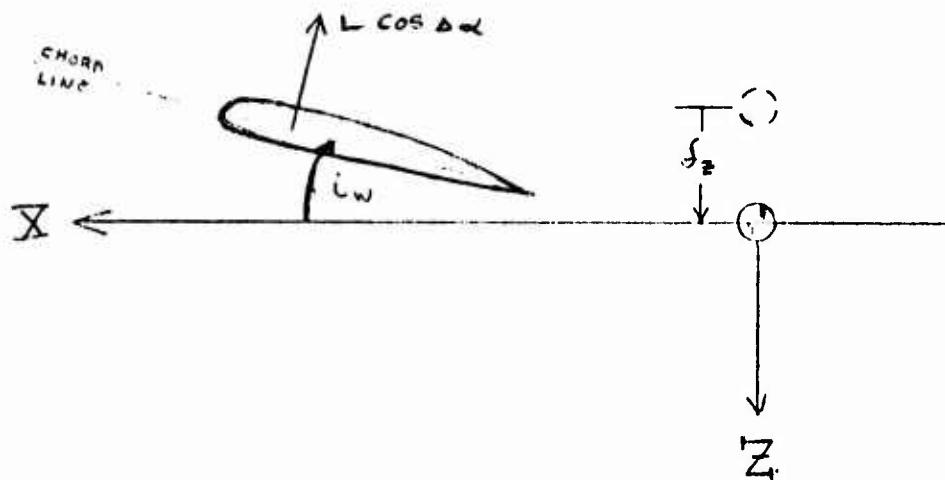

Virtual displacements are:

$$\delta s_x = \delta z \sin \omega - \delta x \cos \omega \\ - \delta \theta [l_2 \cos \omega + l_1 \sin \omega]$$

$$\delta s_z = \delta \beta_H Y_1 - \delta x \sin \omega - \delta z \cos \omega \\ + \delta \theta [Y_1 \sin \delta_3 + X_1 \cos \delta_3 - l_2 \sin \omega + l_1 \cos \omega]$$

$$\delta \phi = \delta \theta - \delta \beta_H \sin \delta_3$$

An example of the virtual work terms is shown below:

If the entire system is displaced  $\delta_z$  then the virtual work ( $F\delta_s$ ) done is =  $L \cos \alpha (\delta_z \cos i_w)$

and  $\frac{\partial W}{\partial z} = L \cos \alpha \cos i_w$

The total virtual work is:

$$W = F_x \delta_{s_x} + F_z \delta_{s_z} + M \delta \rho$$

The following terms were derived in the same manner.

$$EQ(1) \quad Q_{\Theta} = A_7 \dot{\Theta} + A_8 \Theta + A_9 \dot{z} + A_{10} \dot{x} + A_{11} \dot{\beta}_u + A_{12} \beta_u$$

$$EQ(2) \quad Q_{\beta_u} = B_7 \dot{\Theta} + B_8 \Theta + B_9 \dot{z} + B_{10} \dot{x} + B_{11} \dot{\beta}_u + B_{12} \beta_u$$

$$EQ(3) \quad Q_x = C_4 \dot{\Theta} + C_5 \Theta + C_6 \dot{z} + C_7 \dot{x} + C_8 \dot{\beta}_u + C_9 \beta_u$$

$$EQ(4) \quad Q_z = D_4 \dot{\Theta} + D_5 \Theta + D_6 \dot{z} + D_7 \dot{x} + D_8 \dot{\beta}_u + D_9 \beta_u$$

*EQ (1)* Pitching moment equation

*EQ (2)* Wing moment equation about the flapping hinge

*EQ (3)*  $x$  - Force equation

*EQ (4)*  $z$  - Force equation

**APPENDIX B**

GEOMETRY & DISPLACEMENT DIAGRAM

LATERAL-DIRECTIONAL CASE

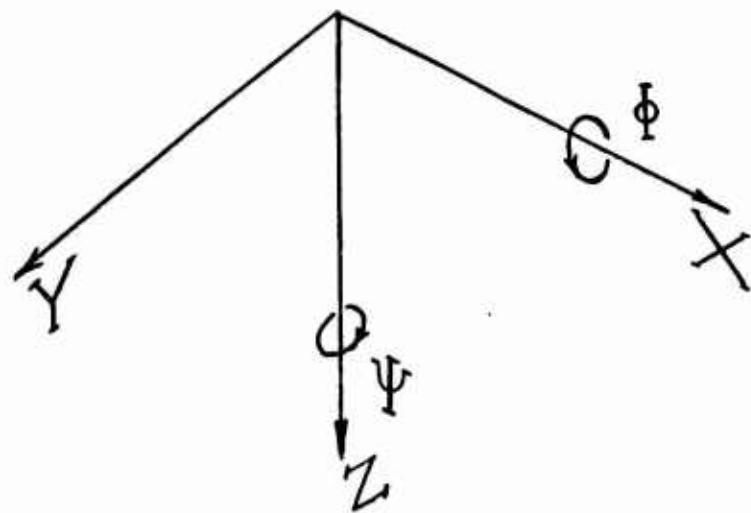

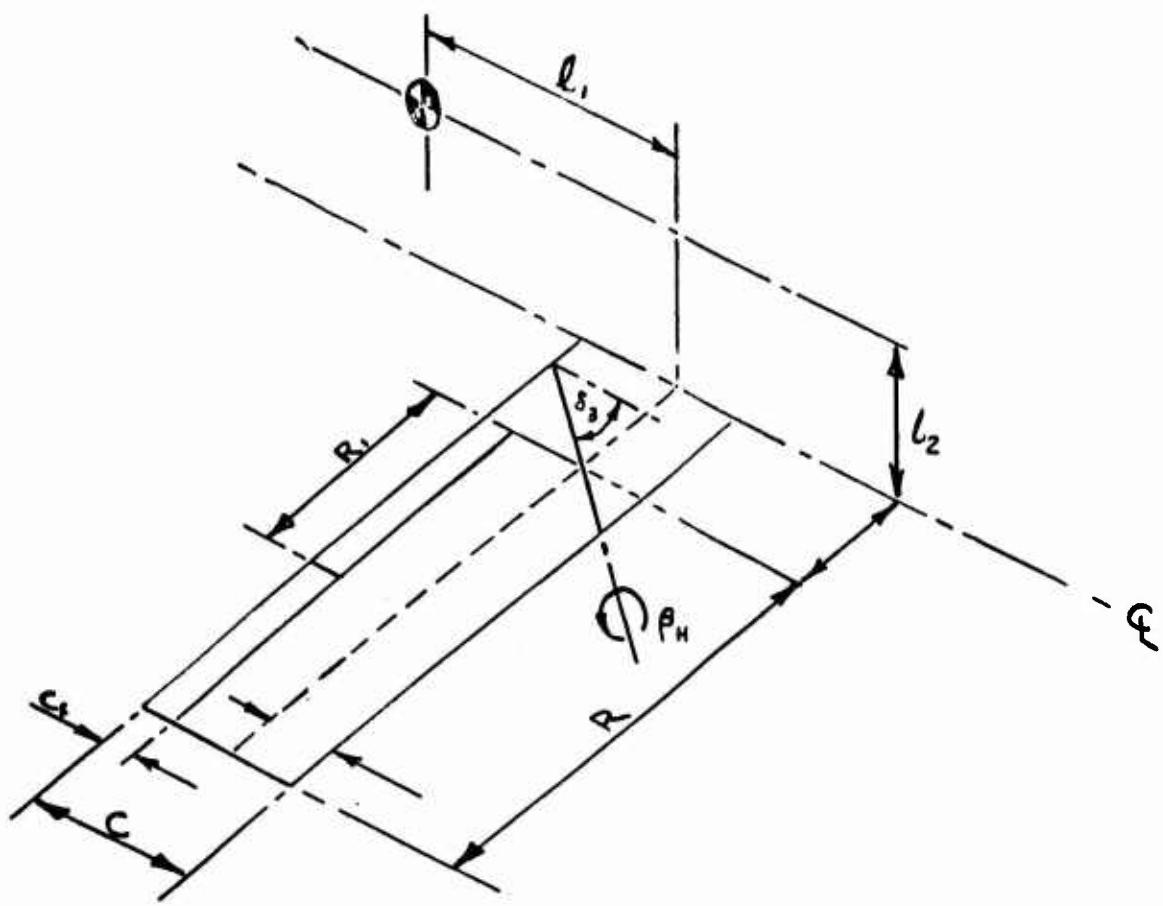

FIGURE 15

## LATERAL-DIRECTIONAL MOTION

### DISPLACEMENT RELATIONSHIPS

Consider the  $y$  &  $z$  displacements of a point at any spanwise location due to a small disturbance  $\delta\phi$  about the roll axis.

$$\delta y = -l_2 \sin \delta\phi + (e+r)(\cos \delta\phi - 1)$$

For small disturbances, we can assume:

$$\sin \phi = \phi$$

$$\cos \phi = 1.$$

$$\delta y = -l_2 \phi.$$

Hence

$$\frac{\partial y}{\partial \phi} = y_\phi = -l_2$$

$$\text{Similarly, } z_\phi = (e+r)$$

$$x_\phi = -(e+r)$$

$$y_\phi = l_1$$

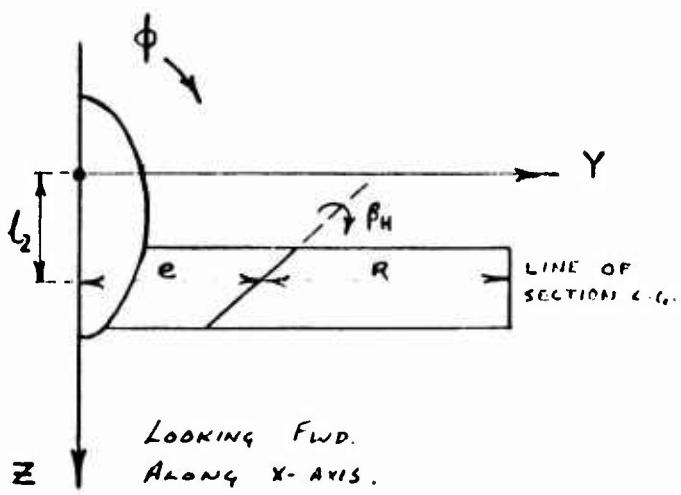

and

$$\theta_\phi = \sin \delta_3$$

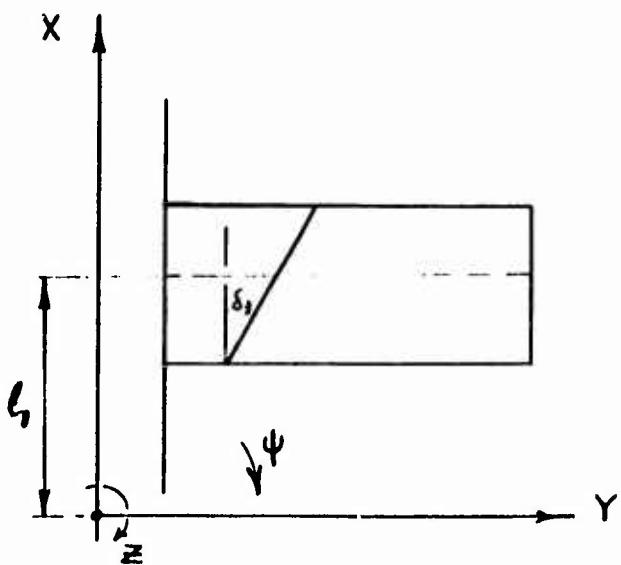

$$x_\beta = r \cos \delta_3 \sin \theta_0$$

$$y_\beta = 0 \quad (\text{for initial } \beta_0 = 0)$$

$$z_\beta = r \cos \delta_3 \cos \theta_0$$

$$\begin{aligned}y_\phi &= -l_2 \\z_\phi &= (e + r)\end{aligned}\quad \textcircled{1}$$

$$\begin{aligned}x_\psi &= -(e + r) \\y_\psi &= l_1\end{aligned}$$

---

$$\begin{aligned}\theta_\beta &= \sin \delta_3 \\x_\beta &= r \cos \delta_3 \sin \theta_0 \\y_\beta &= \text{ZERO} \\z_\beta &= r \cos \delta_3 \cos \theta_0\end{aligned}$$

$\theta_0$  = Angle between Ref. Chord and Ref. Axis

$\Theta_\beta$  = Rate of Change of Incidence with  $\beta$

Expressing the differential displacements in a series.

$$\begin{aligned} dx &= \frac{\partial x}{\partial \phi} d\phi + \frac{\partial x}{\partial \psi} d\psi + \frac{\partial x}{\partial \beta_n} d\beta_n \\ &\equiv x_\phi d\phi + x_\psi d\psi + x_{\beta_n} d\beta_n \end{aligned}$$

Differentiating with respect to time.

$$\begin{aligned} \dot{dx} &= x_\phi \dot{\phi} + x_\psi \dot{\psi} + x_{\beta_n} \dot{\beta}_n \\ \text{and } \dot{dz} &= z_\phi \dot{\phi} + z_\psi \dot{\psi} + z_{\beta_n} \dot{\beta}_n \end{aligned} \quad (2)$$

$x_\phi, x_\psi$  etc. are all constants, being functions only of system geometry.

The above velocity increments are referred to the reference axis system. They must now be referred to a wind axis system in order to determine the total velocities normal and parallel to the free stream.

Resolving normal and parallel to the flight path:

$$\dot{h}_i = -\Delta \ddot{x} \sin \theta_H + \Delta \ddot{z} \cos \theta_H$$

$$\Delta V = \Delta \ddot{x} \cos \theta_H + \Delta \ddot{z} \sin \theta_H$$

$$V_i = V_0 + \Delta V = V_0 + x_\phi \dot{\phi} \cos \theta_H + x_\beta \dot{\beta} \cos \theta_H \\ + z_\phi \dot{\phi} \sin \theta_H + z_\beta \dot{\beta} \sin \theta_H$$

$$\dot{h}_i = -x_\phi \dot{\phi} \sin \theta_H - x_\beta \dot{\beta} \sin \theta_H + z_\phi \dot{\phi} \cos \theta_H + z_\beta \dot{\beta} \cos \theta_H$$

For convenience, we write:

$$V_i = V_0 + c_1 \dot{\phi} + c_2 \dot{\psi} + c_3 \dot{\beta} \quad (3)$$

where  $c_1 = (e+r) \sin \theta_H$

$$c_2 = -(e+r) \cos \theta_H$$

$$c_3 = r \cos \delta_3 \sin(\theta_0 + \theta_H)$$

and  $\dot{h}_i = c_4 \dot{\phi} + c_5 \dot{\psi} + c_6 \dot{\beta} \quad (4)$

where  $c_4 = (e+r) \cos \theta_H$

$$c_5 = (e+r) \sin \theta_H$$

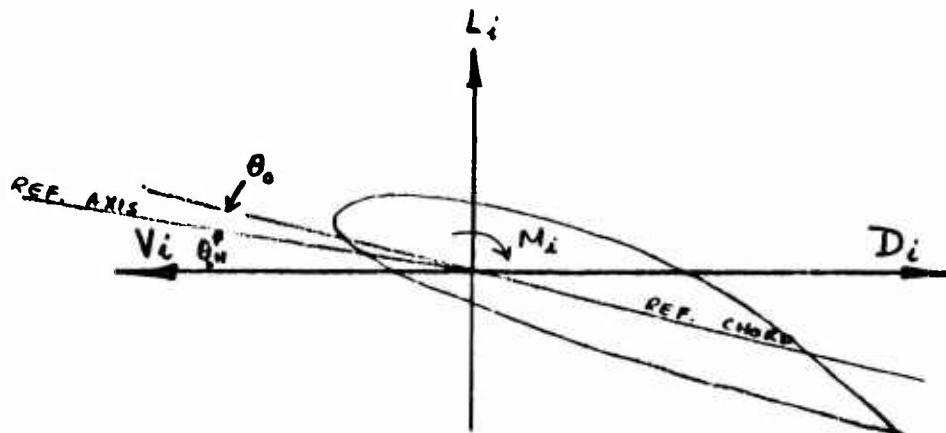

$$c_6 = r \cos \delta_3 \cos(\theta_0 + \theta_H)$$

Squaring terms in Equ. (3), and dropping second order terms, we obtain:

$$V_i^2 = V_0^2 + 2V_0 c_1 \dot{\phi} + 2V_0 c_2 \dot{\psi} + 2V_0 c_3 \dot{\beta}$$

and  $V_i \dot{h}_i = V_0 c_4 \dot{\phi} + V_0 c_5 \dot{\psi} + V_0 c_6 \dot{\beta}$

Aerodynamic Forces and Moments at a general spanwise station:

The steady state angle of attack at the general spanwise station is given by

$$\theta_i = \theta_0 + \theta_H + \beta_H \sin \delta_3 - \alpha_0$$

For any disturbed motion, the angle of attack becomes:

$$\theta_i = \theta + \beta_H \sin \delta_3 - \alpha_0 + \frac{\dot{h}_i}{V_i} \quad (\theta \leq \theta_H + \theta_0)$$

The section lift is given by:

$$\begin{aligned}
 L_i &= \frac{1}{2} \rho V_i^2 a c \left\{ \theta + \beta \sin \delta_3 + \frac{h_i^\circ}{V_0} - \alpha_0 \right\} \\
 &= k_1 V_i^2 \left\{ \theta + \beta \sin \delta_3 - \alpha_0 \right\} + k_1 V_i h_i^\circ \\
 \text{where } k_1 &= \frac{1}{2} \rho a c.
 \end{aligned}$$

Section drag is given by

$$D_i = \frac{1}{2} \rho V_i^2 c \bar{C}_D + \frac{\partial D_i}{\partial \beta_H} \delta \beta_H.$$

The drag coefficient  $\bar{C}_D$  is based on the steady state lift, and the correction term  $\frac{\partial D_i}{\partial \beta_H} \delta \beta_H$  takes account of changes in drag arising from wing flapping disturbances, and is a function of  $S$ , and the flap gearing ratio. The drag coefficient is given by:

$$C_D = C_{D_0} + \frac{k' \bar{C}_L^2}{\pi A R},$$

where  $\bar{C}_L$  = steady state lift coefficient  
we can write the drag in the form

$$\begin{aligned}
 D_i &= k_3 V_i^2 + C_D \beta \frac{1}{2} \rho c V_0^2 \\
 &= k_3 V_0^2 + 2k_3 V_0 C_1 \dot{\phi} + 2k_3 V_0 C_2 \dot{\psi} \\
 &\quad + 2k_3 V_0 C_3 \dot{\beta}_H + \frac{1}{2} \rho c V_0^2 C_D \beta_H
 \end{aligned}$$

$$\text{where } k_3 = \frac{\rho c C_D}{2}$$

For convenience, we write the drag as

$$D_i = C_7 + C_8 \dot{\phi} + C_9 \dot{\psi} + C_{10} \dot{\beta} + C_{11} \beta \quad (5)$$

$$\begin{aligned} \text{where } C_7 &= k_3 V_0^2 & C_9 &= 2k_3 V_0 C_2 & C_{11} &= \frac{\rho c V_0^2}{2} C_D \beta \\ C_8 &= 2k_3 V_0 C_1 & C_{10} &= 2k_3 V_0 C_3 \end{aligned}$$

The lift force can be expanded as follows

$$\begin{aligned} L_i &= k_1 V_i^2 (\theta - \alpha_0) + k_1 V_i^2 \left( \sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta} \right) \beta + k_1 V_i \dot{\beta}_i \\ &= k_1 V_0^2 (\theta - \alpha_0) + 2k_1 V_0 C_1 (\theta - \alpha_0) \dot{\phi} + 2k_1 V_0 C_2 (\theta - \alpha_0) \dot{\psi} \\ &\quad + 2k_1 V_0 C_3 (\theta - \alpha_0) \dot{\beta}_H + k_1 V_0^2 \beta \left( \sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta} \right) \\ &\quad + k_1 V_0 C_4 \dot{\phi} + k_1 V_0 C_5 \dot{\psi} + k_1 V_0 C_6 \dot{\beta}_H \\ &= C_{12} + C_{13} \dot{\phi} + C_{14} \dot{\psi} + C_{15} \dot{\beta}_H + C_{16} \beta_H \quad (6) \end{aligned}$$

$$\begin{aligned} \text{where } C_{12} &= k_1 V_0^2 (\theta - \alpha_0) \\ C_{13} &= (2k_1 V_0 C_1 [\theta - \alpha_0] + k_1 V_0 C_4) \\ C_{14} &= (2k_1 V_0 C_2 [\theta - \alpha_0] + k_1 V_0 C_5) \\ C_{15} &= (2k_1 V_0 C_3 [\theta - \alpha_0] + k_1 V_0 C_6) \\ C_{16} &= k_1 V_0^2 \left( \sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta_H} \right) \end{aligned}$$

The pitching moment equation is:

$$M_i = \frac{1}{2} \rho V_i^2 C^2 \left\{ C_{M_{AC}} + \frac{\partial C_{M_{AC}}}{\partial \beta_H} \beta_H + C_{M_\alpha} (\theta + \beta_H \sin \delta_3 - \alpha_0 - \frac{\partial \alpha_0}{\partial \beta_H} \beta_H + \frac{\dot{\beta}_H}{V_i}) \right\}$$

$$\doteq \frac{1}{2} \rho V_i^2 C^2 (C_{M_{AC}} + C_{M_\alpha} [\theta - \alpha_0])$$

$$+ \frac{1}{2} \rho V_o^2 C^2 \beta \left( \frac{\partial C_{M_{AC}}}{\partial \beta} + C_{M_\alpha} [\sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta}] \right)$$

$$+ \frac{1}{2} \rho V_i \dot{h}_i C^2 C_{M_\alpha}$$

$$= \frac{1}{2} \rho V_o^2 C^2 (C_{M_{AC}} + C_{M_\alpha} [\theta - \alpha_0])$$

$$+ C^2 \rho V_o C_1 (C_{M_{AC}} + C_{M_\alpha} [\theta - \alpha_0]) \dot{\phi}$$

$$+ C^2 \rho V_o C_2 (C_{M_{AC}} + C_{M_\alpha} [\theta - \alpha_0]) \dot{\psi}$$

$$+ C^2 \rho V_o C_3 (C_{M_{AC}} + C_{M_\alpha} [\theta - \alpha_0]) \dot{\beta}_H$$

$$+ \frac{1}{2} C^2 \rho V_o^2 \beta_H \left( \frac{\partial C_{M_{AC}}}{\partial \beta_H} + C_{M_\alpha} [\sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta_H}] \right)$$

$$+ \frac{1}{2} C^2 \rho C_{M_\alpha} V_o C_4 \dot{\phi} + \frac{1}{2} C^2 \rho C_{M_\alpha} V_o C_5 \dot{\psi}$$

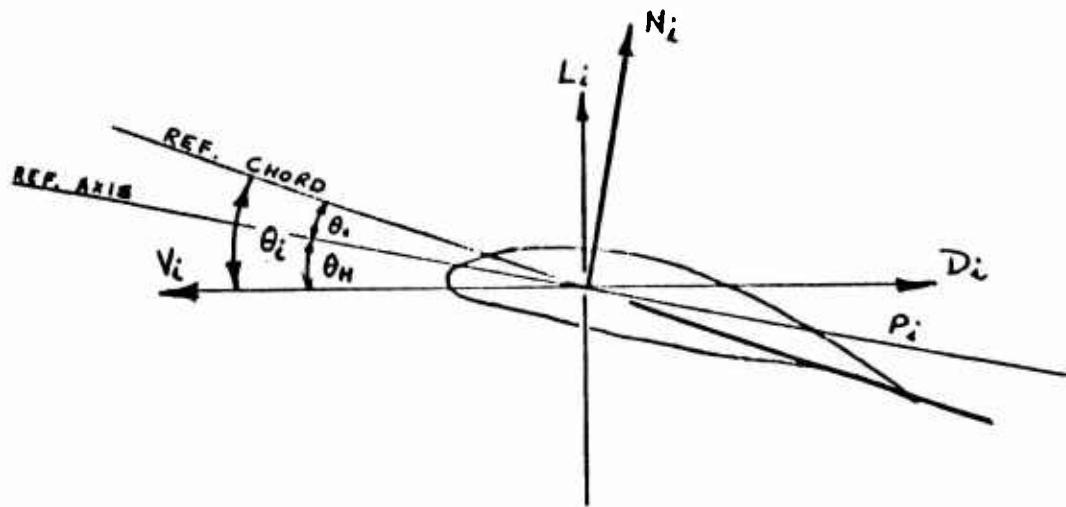

$$+ \frac{1}{2} C^2 \rho C_{M_\alpha} V_o C_6 \dot{\beta}_H$$

$$= C_{18} + C_{19} \dot{\phi} + C_{20} \dot{\psi} + C_{21} \dot{\beta}_H + C_{22} \beta_H \quad (7)$$

where

$$\begin{aligned}
 C_{18} &= \frac{1}{2} C^2 V_0^2 (C_{M_{AC}} + C_{M_\alpha} [\alpha - \alpha_0]) \\
 C_{19} &= C^2 \rho V_0 (C_1 [C_{M_{AC}} + C_{M_\alpha} \{\theta - \alpha_0\}] + \frac{C_{M_\alpha}}{2} C_4) \\
 C_{20} &= C^2 \rho V_0 (C_2 [C_{M_{AC}} + C_{M_\alpha} \{\theta - \alpha_0\}] + \frac{C_{M_\alpha}}{2} C_5) \\
 C_{21} &= C^2 \rho V_0 (C_3 [C_{M_{AC}} + C_{M_\alpha} \{\theta - \alpha_0\}] + \frac{C_{M_\alpha}}{2} C_6) \\
 C_{22} &= \frac{C^2 \rho V_0^2}{2} \left( \frac{\partial C_{M_{AC}}}{\partial \beta_H} + C_{M_\alpha} [\sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta_H}] \right)
 \end{aligned}$$

Finally, resolving back to reference axes,

$$N_i = L_i \cos \theta_H + D_i \sin \theta_H$$

$$P_i = D_i \cos \theta_H - L_i \sin \theta_H$$

$$\begin{aligned}
 N_i &= C_{12} \cos \theta_H + C_7 \sin \theta_H \\
 &+ C_{13} \dot{\phi} \cos \theta_H + C_8 \dot{\phi} \sin \theta_H \quad (+ C_{24} \dot{\phi}) \\
 &+ C_{14} \dot{\psi} \cos \theta_H + C_9 \dot{\psi} \sin \theta_H \quad (+ C_{25} \dot{\psi}) \\
 &+ C_{15} \dot{\beta}_H \cos \theta_H + C_{10} \dot{\beta}_H \sin \theta_H \quad (+ C_{26} \dot{\beta}_H) \\
 &+ C_{16} \beta_H \cos \theta_H + C_{11} \beta_H \sin \theta_H \quad (+ C_{27} \beta_H)
 \end{aligned}$$

$$\begin{aligned}
 P_i = & C_7 \cos \theta_H - C_{12} \sin \theta_H \\
 & + C_8 \dot{\phi} \cos \theta_H - C_{13} \dot{\phi} \sin \theta_H \quad (+ C_{29} \dot{\phi}) \\
 & + C_9 \dot{\psi} \cos \theta_H - C_{14} \dot{\psi} \sin \theta_H \quad (+ C_{30} \dot{\psi}) \\
 & + C_{10} \dot{\beta}_H \cos \theta_H - C_{15} \dot{\beta}_H \sin \theta_H \quad (+ C_{31} \dot{\beta}_H) \\
 & + C_{11} \beta_H \cos \theta_H - C_{16} \beta_H \sin \theta_H \quad (+ C_{32} \beta_H)
 \end{aligned}$$

The total rolling moment due to  $N_i$  is given by:

$$L = - \int_0^e N_i s ds - \int_{e+R_1}^{e+R} N_i s ds \quad (a)$$

where  $e$  = distance of hinge line from fuselage centerline

$R_1$  = spanwise location of break in flap, measured from hinge

$R$  = span of wing outboard of hinge

$s$  = spanwise coordinate, measured from centerline.

The derivatives of  $L$ , with respect to  $\dot{\phi}, \dot{\psi}, \dot{\beta}_H$  and  $\ddot{\beta}_H$  are therefore given by

$$L_{\dot{\phi}} = - \int_0^e C_{24i} s ds - \int_{e+R_1}^{e+R} C_{24o} s ds \quad (a)$$

$$L_{\dot{\psi}} = - \int_0^e C_{25i} s ds - \int_{e+R_1}^{e+R} C_{25o} s ds \quad (b)$$

$$L_{\beta}^i = - \int_e^{e+R_i} C_{26i} s ds - \int_{e+R_i}^{e+R} C_{26o} s ds \quad (c)$$

$$L_{\beta}^o = - \int_e^{e+R_i} C_{27i} s ds - \int_{e+R_i}^{e+R} C_{27o} s ds \quad (d)$$

Subscripts "i" and "o" now denote the inboard and outboard values of the general term  $C_n$

Similarly, the yawing moment derivatives are:

$$N_{\phi}^i = \int_e^{e+R_i} C_{29i} s ds + \int_{e+R_i}^{e+R} C_{29o} s ds \quad (a)$$

$$N_{\phi}^o = \int_e^{e+R_i} C_{30i} s ds + \int_{e+R_i}^{e+R} C_{30o} s ds \quad (b)$$

$$N_{\psi}^i = \int_e^{e+R_i} C_{31i} s ds + \int_{e+R_i}^{e+R} C_{31o} s ds \quad (c)$$

$$N_{\psi}^o = \int_e^{e+R_i} C_{32i} s ds + \int_{e+R_i}^{e+R} C_{32o} s ds \quad (d)$$

The wing hinge moment can be written:

$$M = M_i \sin \delta_3 - P_i r b \cos \delta_3 \sin \theta_0 - N_i r b \cos \delta_3 b \cos \theta_0 \\ = C_{34} + C_{35} \dot{\phi} + C_{36} \dot{\psi} + C_{37} \dot{\beta}_H + C_{38} \beta_H$$

Where:

$$C_{35} = C_{19} \sin \delta_3 - r b \cos \delta_3 (C_8 \sin \theta + C_{13} b \cos \theta)$$

$$C_{36} = C_{20} \sin \delta_3 - r b \cos \delta_3 (C_9 \sin \theta + C_{14} b \cos \theta)$$

$$C_{37} = C_{21} \sin \delta_3 - r b \cos \delta_3 (C_{10} \sin \theta + C_{15} b \cos \theta)$$

$$C_{38} = C_{22} \sin \delta_3 - r b \cos \delta_3 (C_{11} \sin \theta + C_{16} b \cos \theta)$$

Then the hinge moment derivatives are:

$$M_{\dot{\phi}} = \int_0^{R_1} C_{35i} dr + \int_{R_1}^R C_{35o} dr \quad (1) \quad (a)$$

$$M_{\dot{\psi}} = \int_0^{R_1} C_{36i} dr + \int_{R_1}^R C_{36o} dr \quad (b)$$

$$M_{\dot{\beta}_H} = \int_0^{R_1} C_{37i} dr + \int_{R_1}^R C_{37o} dr \quad (c)$$

$$M_{\beta_H} = \int_0^{R_1} C_{38i} dr + \int_{R_1}^R C_{38o} dr \quad (d)$$

### Evaluation of the Integrals

The following damping derivative is given by the expression:

$$L_p^o = - \int_0^{e+r_1} c_{24i} s ds - \int_{e+r_1}^{e+r} c_{24o} s ds$$

$$c_{24} = c_{13} \cos \theta_H + c_8 \sin \theta_H$$

$$= (2k_1 V_0 c_1 [\theta - \alpha_0] + k_1 V_0 c_4) \cos \theta_H + 2k_3 V_0 c_1 \sin \theta_H$$

$$c_1 = (e+r) \sin \theta_H \quad k_1 = \frac{1}{2} \rho ac$$

$$c_4 = (e+r) \cos \theta_H \quad k_3 = \frac{1}{2} \rho c \bar{c}_0$$

$$\begin{aligned} \text{Therefore, } c_{24} &= (e+r) \left( 2k_1 V_0 [\theta - \alpha_0] \sin \theta_H + k_1 V_0 \cos \theta_H \right) \cos \theta_H \\ &\quad + (e+r) (2k_3 V_0 \sin^2 \theta_H) \\ &\equiv C'_{24} (e+r) \end{aligned}$$

$$\text{Thus, } L_p^o = - C'_{24i} \int_0^{e+r_1} (e+r) s ds - C'_{24o} \int_{e+r_1}^{e+r} (e+r) s ds$$

from the definitions of  $e$ ,  $r$  &  $s$ , given in Equ. (8), it can be seen that:

$$e+r \equiv s$$

$$\text{Hence: } L_p^o = - C'_{24i} \int_0^{e+r_1} s^2 ds - C'_{24o} \int_{e+r_1}^{e+r} s^2 ds$$

in a similar manner,

$$L_{\phi}^o = -C'_{25i} \int_0^{e+R_i} s^2 ds - C'_{25o} \int_{e+R_i}^{e+R} s^2 ds$$

The flapping moment derivatives,  $L_{\dot{\theta}}$  &  $L_{\ddot{\theta}}$  are handled as follows:

$$L_{\dot{\theta}}^o = - \int_e^{e+R_i} C_{26i} s ds - \int_{e+R_i}^{e+R} C_{26o} s ds$$

(The lower limit in the first integral becomes 'e', as there is of course no meaning to the integral between  $s=0$  and the location of the hinge at station  $s=e$  )

$$C_{26} = (2k_1 V_0 c_3 [\theta - \alpha_0] + k_1 V_0 c_6) b \omega \theta_H + 2k_3 V_0 c_3 \sin \theta_H$$

$$c_3 = r b \omega \delta_3 \sin \theta$$

$$c_6 = r b \omega \delta_3 b \omega \theta$$

$$\begin{aligned} \text{Hence, } C_{26} &= r b \omega \delta_3 (2k_1 V_0 [\theta - \alpha_0] \sin \theta + k_1 V_0 b \omega \theta) b \omega \theta_H \\ &\quad + r b \omega \delta_3 (2k_3 V_0 \sin \theta \sin \theta_H) \\ &\equiv r C'_{26} \end{aligned}$$

Substituting  $r = s - e$ , the expression for  $L_{\dot{\theta}}$  becomes:

$$L_p^o = -C_{26_i} \int_e^{e+R_1} s(s-e) ds - C_{26_o} \int_{e+R_1}^{e+R} s(s-e) ds$$

The Aerodynamic stiffness derivative is given by the expression:

$$L_p = -C_{27_i} \int_e^{e+R_1} s ds - C_{27_o} \int_{e+R_1}^{e+R} s ds$$

$$\text{and } C_{27} = k_1 V_0^2 \left[ \sin \delta_3 - \frac{\partial \alpha_0}{\partial \beta} \right] \tan \theta_H + \frac{\rho c V^2}{2} \frac{\partial C_D}{\partial \beta} \sin \theta_H$$

The term  $\frac{\partial \alpha_0'}{\partial \beta}$  is the rate of change of section zero lift angle with wing displacement, and is a function of the flap gearing. Likewise, the term  $\frac{\partial C_D}{\partial \beta}$  accounts for

the variation of section drag coefficient with flap gearing.

The derivation of the yawing derivatives is exactly analogous to the foregoing, and without any further work, the formulae are written below:

$$N_\phi^o = C'_{29_i} \int_0^{e+R_1} s^2 ds + C'_{29_o} \int_{e+R_1}^{e+R} s^2 ds$$

$$N_\psi^o = C'_{30_i} \int_0^{e+R_1} s^2 ds + C'_{30_o} \int_{e+R_1}^{e+R} s^2 ds$$

$$N_{\beta}^o = C'_{31_2} \int_e^{e+R_1} s(s-e) ds + C'_{31_0} \int_{e+R_1}^{e+R} s(s-e) ds$$

$$N_{\beta} = C'_{32_2} \int_e^{e+R_1} s ds + C'_{32_0} \int_{e+R_1}^{e+R} s ds$$

$$C'_{29} = \frac{C_{29}}{e+r} \quad C'_{31} = \frac{C_{31}}{r}$$

$$C'_{30} = \frac{C_{30}}{e+r},$$

Expanding the hinge moment derivatives, and again using primes to indicate those terms where the variables ( $r$ ) and ( $e + r$ ) have factored out

$$\begin{aligned} M_{\phi}^o &= C'_{19_i} \sin \delta_3 \int_0^{R_1} (e+r) dr + C'_{19_0} \sin \delta_3 \int_{R_1}^r (e+r) dr \\ &\quad - C'_{8_i} \cos \delta_3 \sin \theta \int_0^{R_1} r(e+r) dr - C'_{8_0} \cos \delta_3 \sin \theta \int_{R_1}^r r(e+r) dr \\ &\quad - C'_{13_i} \cos \delta_3 \cos \theta \int_0^{R_1} r(e+r) dr - C'_{13_0} \cos \delta_3 \cos \theta \int_{R_1}^r r(e+r) dr \end{aligned}$$

$$\begin{aligned} M_{\psi}^o &= C'_{20_i} \sin \delta_3 \int_0^{R_1} (e+r) dr + C'_{20_0} \sin \delta_3 \int_{R_1}^r (e+r) dr \\ &\quad - C'_{9_i} \cos \delta_3 \sin \theta \int_0^{R_1} r(e+r) dr - C'_{9_0} \cos \delta_3 \sin \theta \int_{R_1}^r r(e+r) dr \\ &\quad - C'_{14_i} \cos \delta_3 \cos \theta \int_0^{R_1} r(e+r) dr - C'_{14_0} \cos \delta_3 \cos \theta \int_{R_1}^r r(e+r) dr \end{aligned}$$

$$\begin{aligned}
M_p &= C_{21i}' \sin \delta_3 \int_0^{R_i} r dr + C_{21o}' \sin \delta_3 \int_{R_i}^R r dr \\
&\quad - C_{10i}' \cos \delta_3 \sin \theta \int_0^{R_i} r^2 dr - C_{10o}' \cos \delta_3 \sin \theta \int_{R_i}^R r^2 dr \\
&\quad - C_{15i}' \cos \delta_3 \cos \theta \int_0^{R_i} r^2 dr - C_{15o}' \cos \delta_3 \cos \theta \int_{R_i}^R r^2 dr \\
M_p &= C_{22i}' \sin \delta_3 \int_0^{R_i} dr + C_{22o}' \sin \delta_3 \int_{R_i}^R dr \\
&\quad - C_{11i}' \cos \delta_3 \sin \theta \int_0^{R_i} r dr - C_{11o}' \cos \delta_3 \sin \theta \int_{R_i}^R r dr \\
&\quad - C_{16i}' \cos \delta_3 \cos \theta \int_0^{R_i} r dr - C_{16o}' \cos \delta_3 \cos \theta \int_{R_i}^R r dr
\end{aligned}$$

THE EQUATIONS OF MOTION

In their most general form, the Equations of Motion form the following matrix array:

$$\begin{bmatrix}
 \frac{d\ddot{\phi}}{dt} & (\frac{d\ddot{\psi}}{dt}) & (\frac{d\ddot{\gamma}}{dt}) \\
 (\frac{d\ddot{\psi}}{dt}) & \frac{d\ddot{\psi}}{dt} & (\frac{d\ddot{\gamma}}{dt}) \\
 (\frac{d\ddot{\gamma}}{dt}) & (\frac{d\ddot{\gamma}}{dt}) & \frac{d\ddot{\phi}}{dt}
 \end{bmatrix}
 \begin{bmatrix}
 \ddot{\phi} \\
 \ddot{\psi} \\
 \ddot{\gamma}
 \end{bmatrix}
 +
 \begin{bmatrix}
 \frac{d\dot{\phi}}{dt} & \frac{d\dot{\psi}}{dt} & \frac{d\dot{\gamma}}{dt} \\
 \frac{d\dot{\psi}}{dt} & \frac{d\dot{\psi}}{dt} & \frac{d\dot{\gamma}}{dt} \\
 \frac{d\dot{\gamma}}{dt} & \frac{d\dot{\gamma}}{dt} & \frac{d\dot{\phi}}{dt}
 \end{bmatrix}
 \begin{bmatrix}
 \dot{\phi} \\
 \dot{\psi} \\
 \dot{\gamma}
 \end{bmatrix}
 +
 \begin{bmatrix}
 \ddot{\phi} & \ddot{\psi} & \ddot{\gamma} \\
 \ddot{\psi} & \ddot{\psi} & \ddot{\gamma} \\
 \ddot{\gamma} & \ddot{\gamma} & \ddot{\phi}
 \end{bmatrix}
 \begin{bmatrix}
 \phi \\
 \psi \\
 \gamma
 \end{bmatrix}
 = 0$$

The inertia terms of the first matrix are symmetric about the diagonal indicated. Terms in parentheses are all zero. It will be noticed that the velocity and displacement terms do not form symmetric matrices.

The inertial matrix reduces to:

$$\begin{bmatrix} \frac{\bar{I}_x}{2} & 0 & 0 & I_w \\ 0 & \frac{\bar{I}_z}{2} & 0 & I_w \bar{T}_{\omega} \theta_0 \\ 0 & 0 & \frac{M}{2} & 0 \\ I_w & I_w \bar{T}_{\omega} \theta_0 & 0 & I_p \end{bmatrix} \begin{bmatrix} \phi \\ \psi \\ \gamma \\ \beta \end{bmatrix}$$

where

$\bar{I}_x$  = roll moment of inertia of total rigid system

$\bar{I}_z$  = yaw moment of inertia of total rigid system

$M$  = mass of total rigid system

$\bar{I}_p$  = flapping wing moment of inertia about hinge

$I_w$  = (moment of inertia about an unskewed hinge plus mass moment about same axis times e)  $\cos \delta_3 \cos \theta_0$

### VELOCITY DERIVATIVES

The first two rows of the second matrix are the rolling and yawing moment derivatives with respect to rate of roll, rate of yaw, sideslip velocity and wing flapping velocity.  $\frac{1}{2} \dot{\Psi}$  is the centrifugal force term due to forward velocity and rate of yaw.  $\frac{1}{2} \dot{\Psi} \dot{y}$  is the sideforce due to sideslip. No side-force-terms due to roll rate and wing-flapping velocity appear. The hinge moment derivative  $M_y$  is formally excluded by the initial assumption of a zero initial wing deflection. The only non-zero terms in the displacement matrix ( ~~zero~~ ) are the sideforce due to roll displacement,  $\frac{1}{2} \dot{\Phi}$  and L, N and M derivatives due to ~~phi~~ - all others are identically zero.

The final equations of motion become:

$$\begin{aligned}
 I_x \ddot{\phi} + I_w \dot{\beta}_w &= L \dot{\phi} + L \dot{\psi} \dot{\psi} + L \dot{\gamma} \dot{\gamma} + L \dot{\beta}_w + L \dot{\beta}_w \text{ (roll)} \\
 I_z \ddot{\psi} + I_w \tan \theta \dot{\beta}_w &= N \dot{\phi} + N \dot{\psi} \dot{\phi} + N \dot{\gamma} \dot{\psi} + N \dot{\beta}_w + N \dot{\beta}_w \text{ (yaw)} \\
 I_w \ddot{\phi} + I_p \dot{\beta}_w + I_w \tan \theta_0 \dot{\psi} &= M \dot{\phi} + M \dot{\psi} \dot{\psi} + M \dot{\beta}_w + M \dot{\beta}_w \text{ (wing moment)} \\
 M_z \ddot{\gamma} &= - M_z V_0 \dot{\psi} + Y_p \dot{\gamma} + M_w g \dot{\phi}. \text{ (side force)}
 \end{aligned}$$

Terms in  $\dot{\beta}_w$  and  $\dot{\beta}_w$  are for one wing - all others are half of normal values for a complete system, since we are writing the equations for the right-hand half of the system only, a step justified by the original assumption of anti-symmetry.

RANGE EXTENSION STUDY FOR  
H-21 HELICOPTER FLOATING FUEL WING

RANGE AND TAKE OFF GROSS WEIGHT FOR  
VARIOUS CONFIGURATIONS

CONFIGURATION	RANGE (MILES)	MAX. TAKE OFF WING GROSS WEIGHT (POUNDS)
<u>FORWARD WING</u>		
VARIABLE INCIDENCE	2400	16,000
VARIABLE INCIDENCE	2000	12,100
VARIABLE INCIDENCE WITH DRAG PENALTY ADDED ( $\Delta C_D = +.02$ )	1840	14,800
CONSTANT INCIDENCE	2205	16,000
CONSTANT INCIDENCE	2000	13,700
CONSTANT INCIDENCE WITH DRAG PENALTY ADDED ( $\Delta C_D = +.02$ )	1620	13,800
<u>AFT WING</u>		
VARIABLE INCIDENCE	1975	14,800
CONSTANT INCIDENCE	1840	14,200

TABLE 33

**SUMMARY OF TAKE-OFF PROCEDURES AND RESULTS**  
**FOR FORWARD AND AFT WING POSITION**

PROCEDURE	T.O. SPEED	INITIAL ATTITUDE		TRIM ATTITUDE		DISTANCE BREAKDOWN	FORWARD WING OVER 80' GROSS WT.	AFT WING OVER 80' GROSS WT.	T.O. WING GROSS WT.
		deg	deg	deg	deg				
Trim	70	10	13.5	15	10	13.5	15	6350	7630
Rotate	80	-12	8.5	15	5	8.5	15	1550	3335
Rotate	70	-9	13.5	15	10	13.5	15	1279	2724

TREC 61-106

Vertol Division, The Boeing Company, Morton, Pa., WIND TUNNEL TESTS AND FURTHER ANALYSIS OF THE FLOATING WING FUEL TANKS FOR HELICOPTER RANGE EXTENSION, VOL. 5 - Analysis of Stability, Control and Performance Characteristics by H. Neeb, D. Lawrence, and R. Johnstone, August 1961.

186 pp., incl. illus., tables  
Contract (DA44-177-TC-550)  
USA TRECOM Proj. (9X3B-09-006)

Unclassified Report

This report describes an analytical investigation of the stability and performance of a Boeing-Vertol H-21 tandem rotor helicopter equipped with floating wing fuel cells as a means of ferry range extension. The stability of the total system was studied with the wing located forward and directly under the helicopter center-of-gravity (cg). Two methods of stabilizing the wing oscillations

UNCLASSIFIED

about the hinge were studied: (a) a skewed hinge line, introducing a change in angle of attack as a function of the flapping disturbance, and (b) a geared trailing edge flap, mechanically linked to deflect when the wing flaps. Satisfactory stability was obtained with the wing positioned directly beneath the helicopter cg, using an unskewed hinge line, and geared flaps. The forward wing location was found to be unsatisfactory from the standpoint of longitudinal stability for the light wing case. Flight simulator studies emphasize the need for additional lateral control to supplement that produced by the basic aircraft. It was found that full span differential ailerons with deflections of 2 $\frac{1}{2}$  degrees per inch of stick, provide satisfactory roll control and wing flapping angles. At a take-off weight of 25,900 lbs and with the wing in the aft position the ferry range is 1975 nautical miles.
